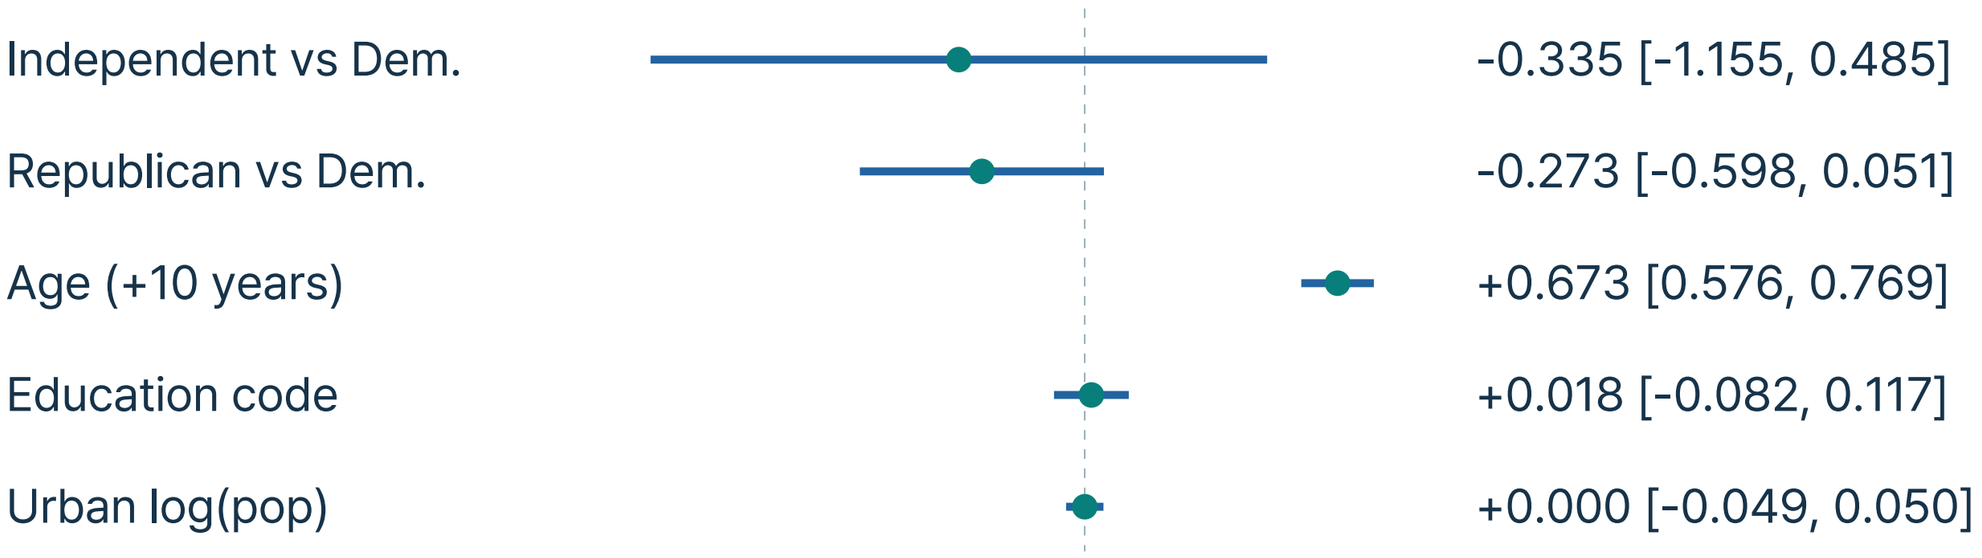
ACHMAGE / EDITORIAL EVIDENCE

Read estimates with their conditions and uncertainty

TV-news frequency · an editorial regression-results example

Design study · 2026-10-20 · Not an institutional announcement

ANES96, N=944. Unstandardized coefficients are shown with 95% confidence intervals. Model R^2=0.170. Results describe conditional associations in the observed sample.



Authored statistical SVG. Pele did not compute the regression or generate these confidence intervals.

01 / Reading order

Points represent coefficients; lines represent 95% CIs. Check the zero reference, units and reference group first. An interval containing zero is not proof of no effect.

02 / Comparison basis

Variable	Unit or reference
Age	10 years
Education	1–7 code
Urban	log(population/1000 + .1)
Party	Democrat reference

03 / Interpretation boundary

Education codes are not guaranteed to have equal intervals. Retain the sampling and unweighted-analysis limitations; do not generalize these associations as population causal effects.

04 / Reproduction record

Estimates and intervals are copied unchanged from the public-data 0.7 analysis cache. This typesetting exercise is not a new statistical recomputation and does not extend the earlier numeric validation.
